

# Distance correlation and distance covariance for data involving binary vectors

Martin Gebert, Miru Lee

**ABSTRACT.** We present known formulas for distance correlation and distance variance specifically for binary vectors. We prove these formulas for the case where the two vectors are binary and the case where only one vector is binary. Our motivation is to enable fast computational algorithms when working with binary vectors. These notes accompany the Rust project `dist_corr` ([https://github.com/mg-gebert/dist\\_corr](https://github.com/mg-gebert/dist_corr)) where the fast algorithms for binary vectors are implemented. Some timing benchmarks are also added.

## 1. Preliminaries

The primary motivation for studying quantities such as distance correlation is to find a computationally convenient test for determining whether two vectors originate from independent probability distributions. In probability theory courses, discussions of independence criterions often begin with the characteristic function of a random variable. This is the Fourier transform of a random variable  $X$ , i.e. for  $t \in \mathbb{R}$

$$\varphi_X(t) = \mathbb{E}[e^{itX}] \quad (1)$$

and also the starting point here. The main relationship with independence of two random variables  $X, Y$  on the same probability space is the following

$$X, Y \text{ independent} \iff \forall s, t \in \mathbb{R} : \varphi_{X,Y}(s, t) = \varphi_X(t)\varphi_Y(s). \quad (2)$$

Integrating the right hand side we see that

$$X, Y \text{ independent} \iff \int_{\mathbb{R}} dt \int_{\mathbb{R}} ds |\varphi_{X,Y}(s, t) - \varphi_X(t)\varphi_Y(s)|^2 \omega(t, s) = 0 \quad (3)$$

for any appropriate weight function  $\omega > 0$  ensuring finiteness of the above integral. The idea in [SRBN07] is to use the weight function

$$\omega(t, s) = \frac{1}{4t^2s^2}. \quad (4)$$

The reason for this choice is simple and very clever as its Fourier transform is

$$\int_{\mathbb{R}} dt e^{-ixt} \frac{1}{|t|^2} = -2|x|. \quad (5)$$

By replacing  $\mathbb{E}$  with the sample average, all of the previous results apply to vectors of samples as well. Hence, given two non-constant vectors  $v, w \in \mathbb{R}^n$  we define the sample

characteristic functions

$$\varphi_{v,w}(t, s) := \frac{1}{n} \sum_{j=1}^n e^{-isv_j} e^{-itw_j} \text{ and } \varphi_v(t) := \frac{1}{n} \sum_{j=1}^n e^{-itv_j}. \quad (6)$$

Then a computation using (5) shows that

$$\int_{\mathbb{R}} dt \int_{\mathbb{R}} ds \frac{|\varphi_{v,w}(s, t) - \varphi_v(t)\varphi_w(s)|^2}{4t^2s^2} = \frac{1}{n^2} \sum_{i=1}^n \sum_{j=1}^n A_{ij} B_{ij} \quad (7)$$

where for  $i, j = 1, \dots, n$

$$A_{ij} = |v_i - v_j| - \frac{1}{n} \sum_{i=1}^n |v_i - v_j| - \frac{1}{n} \sum_{j=1}^n |v_i - v_j| + \frac{1}{n^2} \sum_{i=1}^n \sum_{j=1}^n |v_i - v_j| \quad (8)$$

and  $B_{ij}$  is defined similarly using  $w$ .

Recalling (3), we have now identified a quantity that allows us to infer independence. This leads to the following definition of distance covariance and distance correlation.

**DEFINITION 1.1** (Distance correlation). *Let  $v, w \in \mathbb{R}^n$  be two non-constant vectors. The distance covariance is defined by*

$$dCov(v, w) = \frac{1}{n^2} \sum_{i=1}^n \sum_{j=1}^n A_{ij} B_{ij} \quad (9)$$

and the distance correlation by

$$dCorr(v, w) = \left( \frac{dCov(v, w)}{dCov(v, v)^{1/2} dCov(w, w)^{1/2}} \right)^{\frac{1}{2}} \quad (10)$$

where  $A_{ij}$  and  $B_{ij}$  are defined in (8).

**REMARK 1.1.** *From the derivation of 9 and 10 one sees that*

- (i)  $0 \leq dCorr(v, w) \leq 1$ .
- (ii)  $dCorr(v, w) = 0 \iff v, w$  independent.
- (iii)  $dCorr(v, w) = 1 \iff \exists a, b \in \mathbb{R} : v = aw + b$ , i.e.  $v, w$  linearly dependent.

So far, we have defined the distance correlation for two vectors in  $\mathbb{R}^n$ , meaning vectors of one-dimensional samples. However, distance correlation can also be applied to vectors of higher-dimensional samples by using the Euclidean norm in place of the absolute value in equation (8).

There are various ways to represent the distance covariance. While the formulation (8) in terms of means and grand means of distance matrices is common, it may not always be the most convenient. For instance, it can also be expressed as the trace of a product of appropriate matrices.

**REMARK 1.2.** *Let  $v, w \in \mathbb{R}^n$  be two non-constant vectors and  $D_v := (|v_i - v_j|)_{i,j}$  and  $D_w := (|w_i - w_j|)_{i,j}$  be the corresponding distance matrices. Let  $\varphi = (1/\sqrt{n}, \dots, 1/\sqrt{n})^T \in \mathbb{R}^n$  then one can rewrite  $A$  defined in (7) according to*

$$A = D_v - |\varphi\rangle\langle D_v\varphi| - |D_v\varphi\rangle\langle\varphi| + |\varphi\rangle\langle\varphi|\langle\varphi, D_v\varphi\rangle \quad (11)$$

and  $B$  along the same lines in terms of  $D_w$ . Using this, we obtain

$$\begin{aligned} dCov(v, w) &= \frac{1}{n^2} \text{Tr}(P^\perp D_v P^\perp D_w P^\perp) \\ &= \frac{1}{n^2} \text{Tr}(D_v D_w) - \frac{2}{n^2} \langle D_v \varphi, D_w \varphi \rangle + \frac{1}{n^2} \langle \varphi, D_v \varphi \rangle \langle \varphi, D_w \varphi \rangle. \end{aligned} \quad (12)$$

where  $P^\perp$  is the orthogonal projection onto the orthogonal complement of the subspace spanned by the vector  $\varphi$ , i.e. in bar-ket notation  $P^\perp = id - |\varphi\rangle\langle\varphi|$  with  $id$  being the identity matrix and  $\text{Tr}$  denotes the trace of a matrix.

A key fact for what follows is that if  $v \in \mathbb{R}^n$  is a binary vector then the distance matrix  $D_v$  can be simplified.

LEMMA 1.2. Let  $v \in \mathbb{R}^n$  be a 0-1-valued binary vector, i.e.  $v_i \in \{0, 1\}$ . Define  $\tilde{v} \in \mathbb{R}^n$  by  $\tilde{v}_i = 2v_i - 1 \in \{-1, 1\}$  and  $\tilde{\varphi} = (1, \dots, 1)^T \in \mathbb{R}^n$ . Then

$$D_v = \frac{1}{2} \left( |\tilde{\varphi}\rangle\langle\tilde{\varphi}| - |\tilde{v}\rangle\langle\tilde{v}| \right), \quad (13)$$

i.e. the distance matrix can be represented as a rank-2 matrix.

## 2. Distance Covariance for two binary vectors

Let  $v, w \in \mathbb{R}^d$  be two binary vectors, i.e. vectors which take on only two different values, for simplicity we assume  $v_i, w_i \in \{0, 1\}$  for all  $i = 1, \dots, n$ . In this case the formula for the distance correlation can be simplified considerably and one obtains the following.

THEOREM 2.1. Let  $v, w \in \mathbb{R}^n$  such that  $v_i, w_i \in \{0, 1\}$  for all  $i = 1, \dots, n$ . We define the confusion matrix corresponding to the pair  $v, w$

	$w_i = 1$	$w_i = 0$	$\Sigma$
$v_i = 1$	$n_{11}$	$n_{10}$	$n_{1-}$
$v_i = 0$	$n_{01}$	$n_{00}$	$n_{0-}$
$\Sigma$	$n_{-1}$	$n_{-0}$	$n$

Then

$$dCov(v, w) = \frac{4}{n^4} (n_{11}n_{00} - n_{10}n_{01})^2 \quad (14)$$

and

$$dCorr(v, w) = \frac{n_{11}n_{00} - n_{10}n_{01}}{n_{1-}n_{-1}n_{0-}n_{-0}}. \quad (15)$$

REMARK 2.1. The above formula for the distance correlation is known and turns out to be similar to the Phi coefficient, see [wikipedia: Phi coefficient](#).

PROOF OF THEOREM 2.1. Let  $\varphi := \frac{1}{\sqrt{n}}(1, \dots, 1)^T \in \mathbb{R}^n$  and  $\tilde{v}, \tilde{w} \in \mathbb{R}^n$  are defined by  $\tilde{v}_i := 2v_i - 1$ ,  $\tilde{w}_i := 2w_i - 1$ . Using the representation of the distance covariance (12) and (13), we obtain

$$\begin{aligned} dCov(v, w) &= \frac{1}{n^2} \text{Tr}(P^\perp D_v P^\perp D_w P^\perp) \\ &= \frac{1}{4n^2} \langle \tilde{v}, P^\perp \tilde{w} \rangle \langle \tilde{w}, P^\perp \tilde{v} \rangle \\ &= \frac{1}{4n^2} (\langle \tilde{v}, \tilde{w} \rangle - \langle \tilde{v}, \varphi \rangle \langle \varphi, \tilde{w} \rangle)^2 \end{aligned} \quad (16)$$

where we used  $P^\perp \tilde{\varphi} = 0$ . We write the latter scalar products in terms of  $n_{11}, n_{10}, \dots$  and get

$$\begin{aligned} (16) &= \frac{1}{4n^2} \left( n_{11} + n_{00} - n_{10} - n_{01} - \frac{1}{n} (n_{1-} - n_{0-})(n_{-1} - n_{-0}) \right)^2 \\ &= \frac{1}{4n^4} \left( ((n_{11} + n_{00})^2 - (n_{10} + n_{01})^2) \right. \\ &\quad \left. - (n_{11} - n_{00} + n_{10} - n_{01})(n_{11} - n_{00} + n_{01} - n_{10}) \right)^2 \end{aligned} \quad (17)$$

where we wrote out  $n = n_{11} + n_{10} + n_{01} + n_{00}$ ,  $n_{1-} = n_{11} + n_{10}$  and  $n_{0-}, n_{-1}, n_{-0}$  accordingly. Rewriting the latter further we end up with

$$\begin{aligned} (17) &= \frac{1}{4n^4} \left( ((n_{11} + n_{00})^2 - (n_{10} + n_{01})^2) - (n_{11} - n_{00})^2 + (n_{10} - n_{01})^2 \right)^2 \\ &= \frac{1}{4n^4} \left( 4n_{11}n_{00} - 4n_{10}n_{01} \right)^2. \end{aligned} \quad (18)$$

The formula for  $dCorr$  follows from applying the above formula to (10).  $\square$

### 3. Distance Covariance involving one binary vector

Let  $v \in \mathbb{R}^d$  be a binary vector, i.e.  $v_i \in \{0, 1\}$  for all  $i = 1, \dots, n$  and some arbitrary  $w \in \mathbb{R}^d$ . In this case the formula for the distance correlation can also be simplified and one obtains the following.

**THEOREM 3.1.** *Let  $v \in \mathbb{R}^n$  be such that  $v_i \in \{0, 1\}$  for all  $i = 1, \dots, n$  and  $w \in \mathbb{R}^d$ . Then*

$$dCov(v, w) = -\frac{1}{2n^2} \langle P^\perp \tilde{v}, D_w P^\perp \tilde{v} \rangle \quad (19)$$

where  $\tilde{v} \in \mathbb{R}^n$  is defined by  $\tilde{v}_i := 2v_i - 1$ ,  $D_w := (|w_i - w_j|)_{i,j}$  is the distance matrix corresponding to  $w$  and  $P^\perp = id - |\varphi\rangle\langle\varphi|$  with  $\varphi := \frac{1}{\sqrt{n}}(1, \dots, 1)^T \in \mathbb{R}^n$ .

**PROOF.** Using the representation (13) of  $D_v$  for binary  $v$  and  $P^\perp \tilde{\varphi} = 0$ , we obtain

$$\begin{aligned} dCov(v, w) &= \frac{1}{2n^2} \text{Tr}(P^\perp D_v P^\perp D_w P^\perp) \\ &= -\frac{1}{2n^2} \langle P^\perp \tilde{v}, D_w P^\perp \tilde{v} \rangle. \end{aligned} \quad (20)$$

$\square$

**REMARK 3.1.** *The vector  $P^\perp \tilde{v} = \tilde{v} - \langle \tilde{v}, \varphi \rangle \varphi$  can be computed in  $O(n)$ . For an increasingly sorted  $w$  also  $\langle u, D_w u \rangle$  can be computed in  $O(n)$ . This implies that the computational complexity of (19) is  $O(n \log n)$  and the extension by  $\log n$  stems from sorting the vector  $w$  increasingly. This implies that for one binary vector, the algorithm described above is simpler and faster than the standard  $O(n \log(n))$  algorithm for two arbitrary vectors, see [CH19]. In the next section we underline with numerical evidence.*

### 4. Performance speed

In this section we evaluate the performance of the  $O(n \log n)$  algorithm from [CH19] against improved implementations that take advantage of cases in which one or both input vectors are binary-valued. Benchmarking was performed on a Windows system equipped with an AMD Ryzen 7 PRO 6850U processor and 32 GB of RAM

and using the implementation from our Rust project `dist_corr` ([https://github.com/mgembert/dist\\_corr](https://github.com/mgembert/dist_corr)).

**4.1. One binary vector.** We generate pairs  $(v_1, v_2)$  of vectors of length  $n$  where the first vector  $v_1$  is randomly chosen within  $[-10, 10]$  and the companion vector  $v_2$  is defined by

$$v_2(j) := \begin{cases} 1.0, & \text{if } v_1(j) < 0.0, \\ 0.0, & \text{otherwise,} \end{cases}$$

for  $j = 1, \dots, n$ . This means we compare a general float vector with a binary vector. We compute the distance correlation for various lengths  $n = 2^m$  for  $m = 6, 8, 10, 12, 14, 16, 18, 20, 22$  for

1. the standard  $O(n \log(n))$  algorithm outlined in [CH19].
2. the semi-binary  $O(n \log(n))$  algorithm for one binary vector outlined in Section 3.

TABLE 1. Benchmark median running times (seconds) for general float vs binary

$n$	standard (s)	semi-binary (s)
$2^6$	$3.8514 \times 10^{-6}$	$1.2830 \times 10^{-6}$
$2^8$	$1.93810 \times 10^{-5}$	$0.57068 \times 10^{-5}$
$2^{10}$	$9.70580 \times 10^{-5}$	$2.79640 \times 10^{-5}$
$2^{12}$	$4.486000 \times 10^{-4}$	$1.313100 \times 10^{-4}$
$2^{14}$	$1.652700 \times 10^{-3}$	$5.121000 \times 10^{-4}$
$2^{16}$	$9.675100 \times 10^{-3}$	$2.068600 \times 10^{-3}$
$2^{18}$	$4.708400 \times 10^{-2}$	$1.064600 \times 10^{-2}$
$2^{20}$	$2.961400 \times 10^{-1}$	$0.4855400 \times 10^{-1}$
$2^{22}$	$1.504900 \times 10^0$	$0.2533500 \times 10^0$

**4.2. Two binary vectors.** We generate pairs of vectors  $(v_1, v_2)$  of length  $n$ . The first vector  $v_1$  is a random binary vector, i.e. 0-1-valued, where the probability of 0 and 1 are 0.5. The companion vector  $v_2$  is defined by

$$v_2(j) := \begin{cases} v_1(j), & \text{if } 2 \mid v_1(j), \\ 0.0, & \text{otherwise,} \end{cases}$$

for  $j = 1, \dots, n$ . This means we compare two binary vectors. We compute the distance correlation for various lengths  $n = 2^m$  for  $m = 6, 8, 10, 12, 14, 16, 18, 20, 22$  for

1. the standard  $O(n \log(n))$  algorithm outlined in [CH19].
2. the semi-binary  $O(n \log(n))$  algorithm for one binary vector outlined in Section 3. We call this semi-binary.
3. the full-binary  $O(n)$  algorithm for two binary vectors outlined in Section 2.

TABLE 2. Benchmark median running times (seconds) for binary vs binary.

$n$	standard (s)	semi-binary (s)	full-binary (s)
$2^6$	$3.3123 \times 10^{-6}$	$0.8548 \times 10^{-6}$	$0.0656 \times 10^{-6}$
$2^8$	$1.4228 \times 10^{-5}$	$0.3175 \times 10^{-5}$	$0.0258 \times 10^{-5}$
$2^{10}$	$6.6114 \times 10^{-5}$	$1.1531 \times 10^{-5}$	$0.1144 \times 10^{-5}$
$2^{12}$	$2.7786 \times 10^{-4}$	$0.6089 \times 10^{-4}$	$0.0475 \times 10^{-4}$
$2^{14}$	$1.0255 \times 10^{-3}$	$0.2861 \times 10^{-3}$	$0.0452 \times 10^{-3}$
$2^{16}$	$4.7995 \times 10^{-3}$	$1.2748 \times 10^{-3}$	$0.2663 \times 10^{-3}$
$2^{18}$	$2.4360 \times 10^{-2}$	$0.8102 \times 10^{-2}$	$0.1084 \times 10^{-2}$
$2^{20}$	$1.3763 \times 10^{-1}$	$0.2827 \times 10^{-1}$	$0.0438 \times 10^{-1}$
$2^{22}$	$6.2279 \times 10^{-1}$	$1.1863 \times 10^{-1}$	$0.1749 \times 10^{-1}$
